

Dynamical Ejecta from Binary Neutron Star Mergers

David Radice¹

¹ Walter Burke Fellow

Collaborators: S. Bernuzzi, F. Galeazzi, J. Lippuner, P. Mösta,
L. Roberts, C. D. Ott, L. Rezzolla

Background

- Dynamical ejecta: outflow during merger
- Consequences: nucleosynthesis? EM counterparts?

See also talks by Dietrich, Branchesi, Metzger

Open Questions

- Ejection: tides or shocks?
- Composition, morphology?
- Impact of weak reactions? EOS?
- NSNS mergers: the origin of r-process elements?

Methods: WhiskyTHC

- GRHD: **MP5**+HLLE
- Gravity: BSSN or Z4c
- Tabulated nuclear EOS
- Neutrino **cooling** and **heating**

THC = Templated Hydrodynamics Code

Ejection Mechanisms

EOS: LS220 $M = 1.38 M_{\odot}$

Impact of Weak Interactions

EOS: LS220 $M = 1.38 M_{\odot}$

- The yields are robust for $A > 120$
- $A < 120$: needs $Y_e > 0.25$, critical role of neutrinos

Outflow Morphology

EOS: LS220 $M = 1.38 M_{\odot}$

- Ejecta mostly contained within 60° of orbital plane
- Mildly relativistic velocities

Impact of Equation of State

EOS: DD2, LS220, SFHo $M = 1.35 M_{\odot}$

- EOS impacts composition and mass
- The yields for $A > 120$ are robust; 1st peak underproduced

Total Ejected Mass

EOS: SFHo $M = 1.35 M_{\odot}$

Simulation	Cooling	Heating	Ejecta Mass [Msun]
WhiskyTHC	x	-	3.5×10^{-3}
Palenzuela+ 2015	x	-	3.2×10^{-3}
Bauswein+ 2013	-	-	4.8×10^{-3}
Sekiguchi+ 2015	x	-	10.0×10^{-3}
Sekiguchi+ 2015	x	x	11.0×10^{-3}

Large uncertainty in the ejecta mass!

Conclusions

- Outflows driven by tidal torques, shocks, and neutrino radiation
- Robustly produce 2nd and 3rd peak r-process elements; 1st peak still unclear
- Still some work do to (better HD, radiation, MHD, disk winds, ...)

Impact of Orbital Dynamics

EOS: LS220 $M = 1.38 M_{\odot}$

- Neutrino cooling decreases ejecta mass by $\sim 1/2$
- Eccentric mergers can eject significantly more mass
